DO Not Use This Page for Writing Answers

1 A.

Public Blockchain.

A Block chain is a distributed ledger technology.

Advantages.

- Any One with good hardware and internet can access.
- Decentralized
- No Higher authority
- Transparency.
- Online Identity Verification.

B.

Bitcoin. → Crypto Coin.

Bitcoin uses Proof of work, as if one person does work then he is rewarded for his work. These people are called Miners, miners solve complex algorithms and for their work a coin is given. This coin is also used as currency. This crypto coin has many benefits. Generally A Bitcoin is a distributed ledger technology.

C

Private Block chain.

A Private Block chain is a distributed ledger technology which means is 'Private', not everyone can access it.

A Private Blockchain is ~~mainly~~ created by a single company so ~~it~~ only its employees can join it and do their work.

To join the Blockchain you'll need special authorization. As this Blockchain is generally have ^{limited} number of nodes joining it it is comparatively faster than public.

D

Bitcoin

Bitcoin is a distributed ledger technology platform which is used for various things. Bitcoin follows Proof of work system ensuring each user is rewarded for their work. As Bitcoin is transparent and public it can also be used as an online Identity verification. Bitcoin is secured and takes its measures to avoid double spending problem.

E

Ether. ETH

Ethereum is a distributed ledger technology platform which is vastly known to all. Its crypto coin is called ETH, users can obtain this ETH by mining. Mining is the process of solving complex algorithms. Each miner is rewarded by a certain amount of ETH. Ethereum uses Proof of work system so a miner is rewarded only after his work is proven. For all this the ETH crypto coin can be used as a currency.

F

Blockchain Technology Services.

As Blockchain can be used as a currency and it is decentralized. There are ^{no} ~~limited~~ boundaries for ways of payment. It can be done over seas and there won't be any higher authority to question about your payments. A great example at this is IOTA. It is the mix of IoT and crypto coin. Two machines can communicate with each other through IoT and authorize payment between each other without any question. Financial services can also be used in the medical field.

2 A]

Bitcoin:

Bitcoin is one of the types in blockchains. It is a distributed ledger technology platform.

Bitcoin uses Proof of Work system to authenticate payments from its users. Its users also known as nodes are connected to the blockchain Bitcoin as a whole.

Bitcoin is transparent so that means what ever activity which happened on the blockchain is accessible and visible to the whole. That's it is public there is no sense of privacy.

For a new block to add to the chain it need to outlast and miners need to solve complex algorithms.

After a block is added there is no chance of changing it. The data is now forever as it is.

A wallet is required to store crypto coin.

B]

Wallets.

A wallet is what it describes for as in blockchain.

A wallet stores currency, so in this case it stores crypto coin / crypto currency.

Without a wallet you can't store the rewarded coins for your work. As miners each miner must maintain a wallet.

→ Mobile wallet

A mobile wallet is storing all the necessary details to connect to blockchain and your account details on a mobile phone.

→ Physical wallet

It is storing all the details to connect to blockchain and your account details on physical paper.

C

Smart Contracts.

Block chain is a distributed ledger technology. And for the block chain there will be miners.

A miners job is to solve complex algorithms to authorize all transactions. For Block chain uses Proof of Work system. As it has that for each miner he is rewarded with crypto coin.

A smart contract is a digital agreement stating that if a certain job is completed they shall be rewarded for their work.

So if a miner completes his work and he is rewarded for solving complex algorithms that is a smart contract stating he is rewarded if his job is completed.

D

Financial Services.

Block chain is a distributed ledger technology platform.

As for each Block chain there will be its own crypto coin.

This coin can be used as currency and means of payment. The advantage with this crypto coin is that as block chain is ~~de~~ decentralized there will be no higher authority to look into your transaction. Also you can have payment transactions overseas without any disturbances.

An example about this is IOTA.

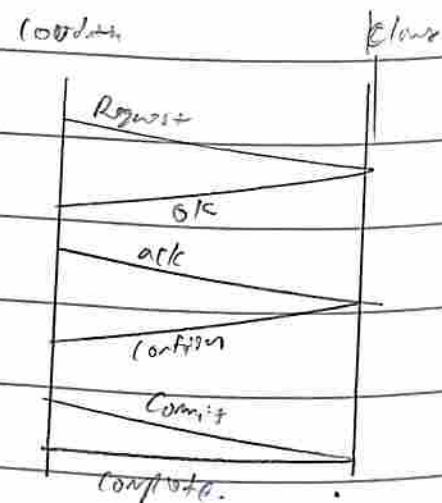

As we know in IOT two or more machines can communicate with each other. They are many benefits with IOT. So if these IOT machines are connected to the Block chain then they can themselves authorize payments for each other and communicate. With Block chain being decentralized there is no issue of higher authority checking.

3 A

Three Phase Commit 3PC

There are 3 phases in 3PC

- Request
- Acknowledgment
- Commit

A three phase commit is used for acknowledging everyone connected together about a change being to be committed.

This 3PC is mainly used in large scale servers.

With 3PC data integrity is maintained as there is no chance of data to be outdated or overwritten.

Request → Communication for a data change

Ack → Informing everyone about the change

Commit → committing to the change

B

Bitcoin.

Bitcoin is a distributed ledger technology platform.

Bitcoin is one of the many types of cryptocurrency in block chains.

Bitcoin is ~~mostly~~ known to many people and it's simple to connect to it. Any one with good hardware and internet can connect to it. It is also a Public Blockchain so it is transparent every where. Every action done in it is visible to everyone. This ~~means~~ ^{means} there is no privacy.

It is important as there are many miners solving complex problems for their reward as of Bitcoin. Each miner has to solve complex algorithms, authentication transactions and for their work they are rewarded.

Bitcoin uses proof of work system. So that every coin is unique and can't be duplicated. Even if we try to duplicate the block chain has a public list of each coin.

5. A

Supply chain management System.

Blockchain is a distributed ledger Technology platform.

For each Blockchain there will be a crypto coin.
This coin can be used as currency. Also as a form of payment.

For a new coin to be mined A miner must complete his work. Blockchains use Proof of Work System.

A miner solves complex algorithms and for solving it they are rewarded with coin.

As a miner shows his proof of work his reward coin is generated.

This way of generating coin is in the supply chain. When a coin is mined its coin is added to the Blockchain.

B

Health care

Block chain is a distributed ledger technology.

As Block chain is sometimes public, sometimes private.
But for a Public Blockchain every thing is transparent.
As it's transparent that means it needs to be verified - properly add authorized ones for a single user.
It can also be used as an online ~~Identification~~ Identity verification.
Online Identity verification.

For it using Smart Contract in medical Industry can be improved as each user will be verified and their means of payment is verified.

Blockchain transactions are better because as Blockchain is decentralized there is no higher authority to judge the payment. And transactions can be done ourselves without any issue.
